

# The Power & Density Pivot: U.S. Data Center Market Outlook (2025–2030)

From cloud-scale connectivity to the physics of AI infrastructure.

# Unprecedented demand is colliding with critical infrastructure bottlenecks.

## The Boom

### Record-Breaking Absorption.

Total capacity in primary markets reached **6.9 GW** (+34% YoY). Construction pipelines have **doubled** to **6.35 GW**, driven by hyperscale expansion.

## The Shift

### Geography is Fluid.

For the first time, **Atlanta (706 MW)** outpaced Northern Virginia (**452 MW**) in net absorption. **Power availability** now dictates location strategy.

## The Constraint

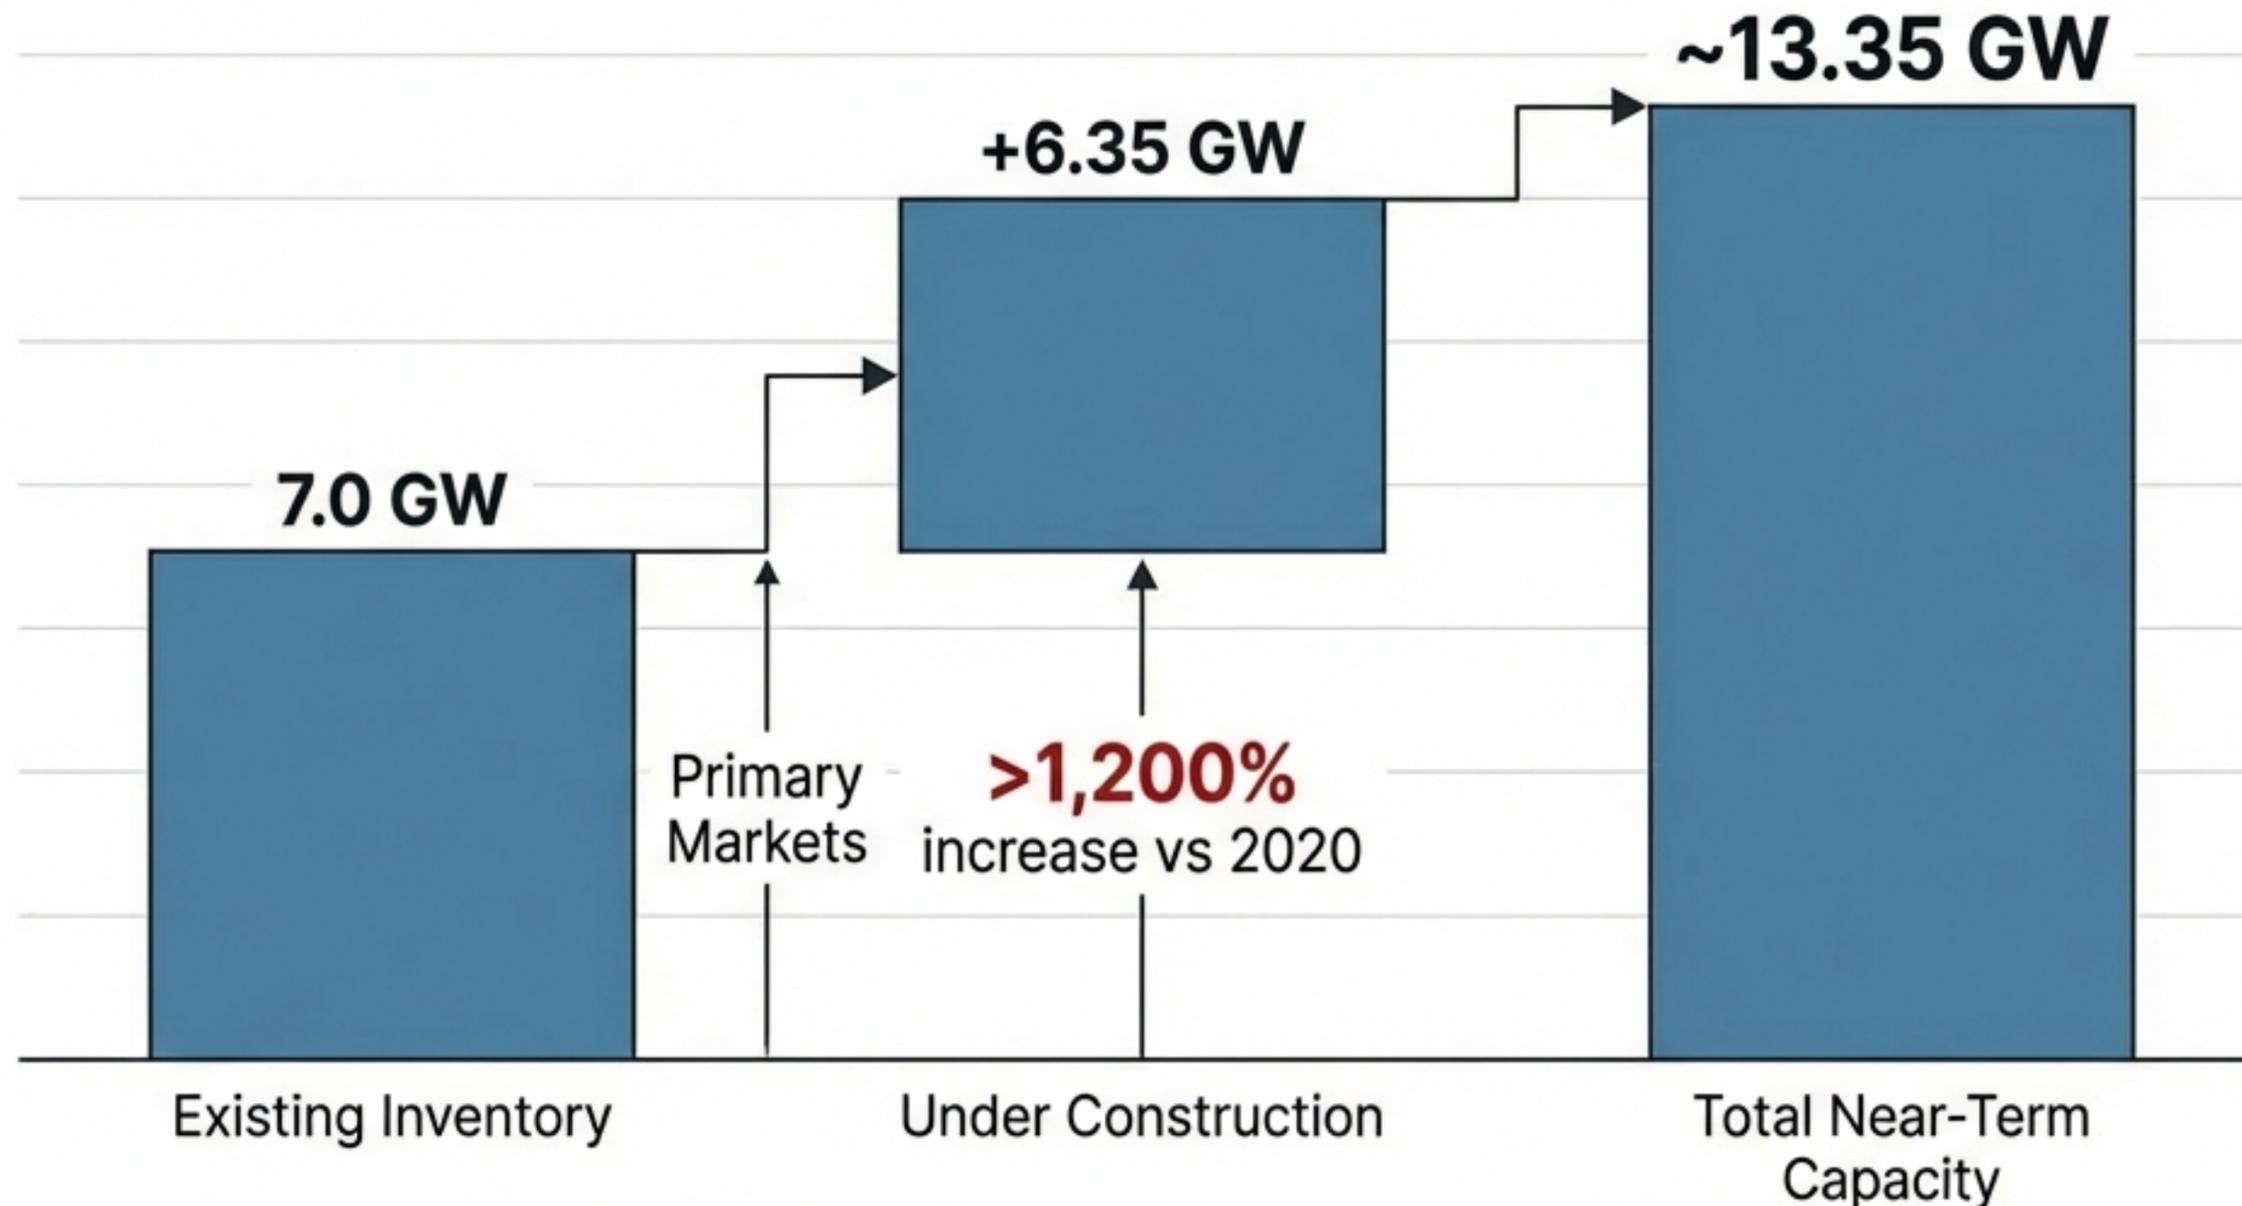

### The Grid Governor.

Vacancy is **<1.9%**, but power delivery timelines have stretched to **4+ years in key hubs**. The market is no longer demand-constrained; it is **time-to-power constrained**.

# The U.S. remains the global epicenter of digital infrastructure with a \$100B+ valuation.

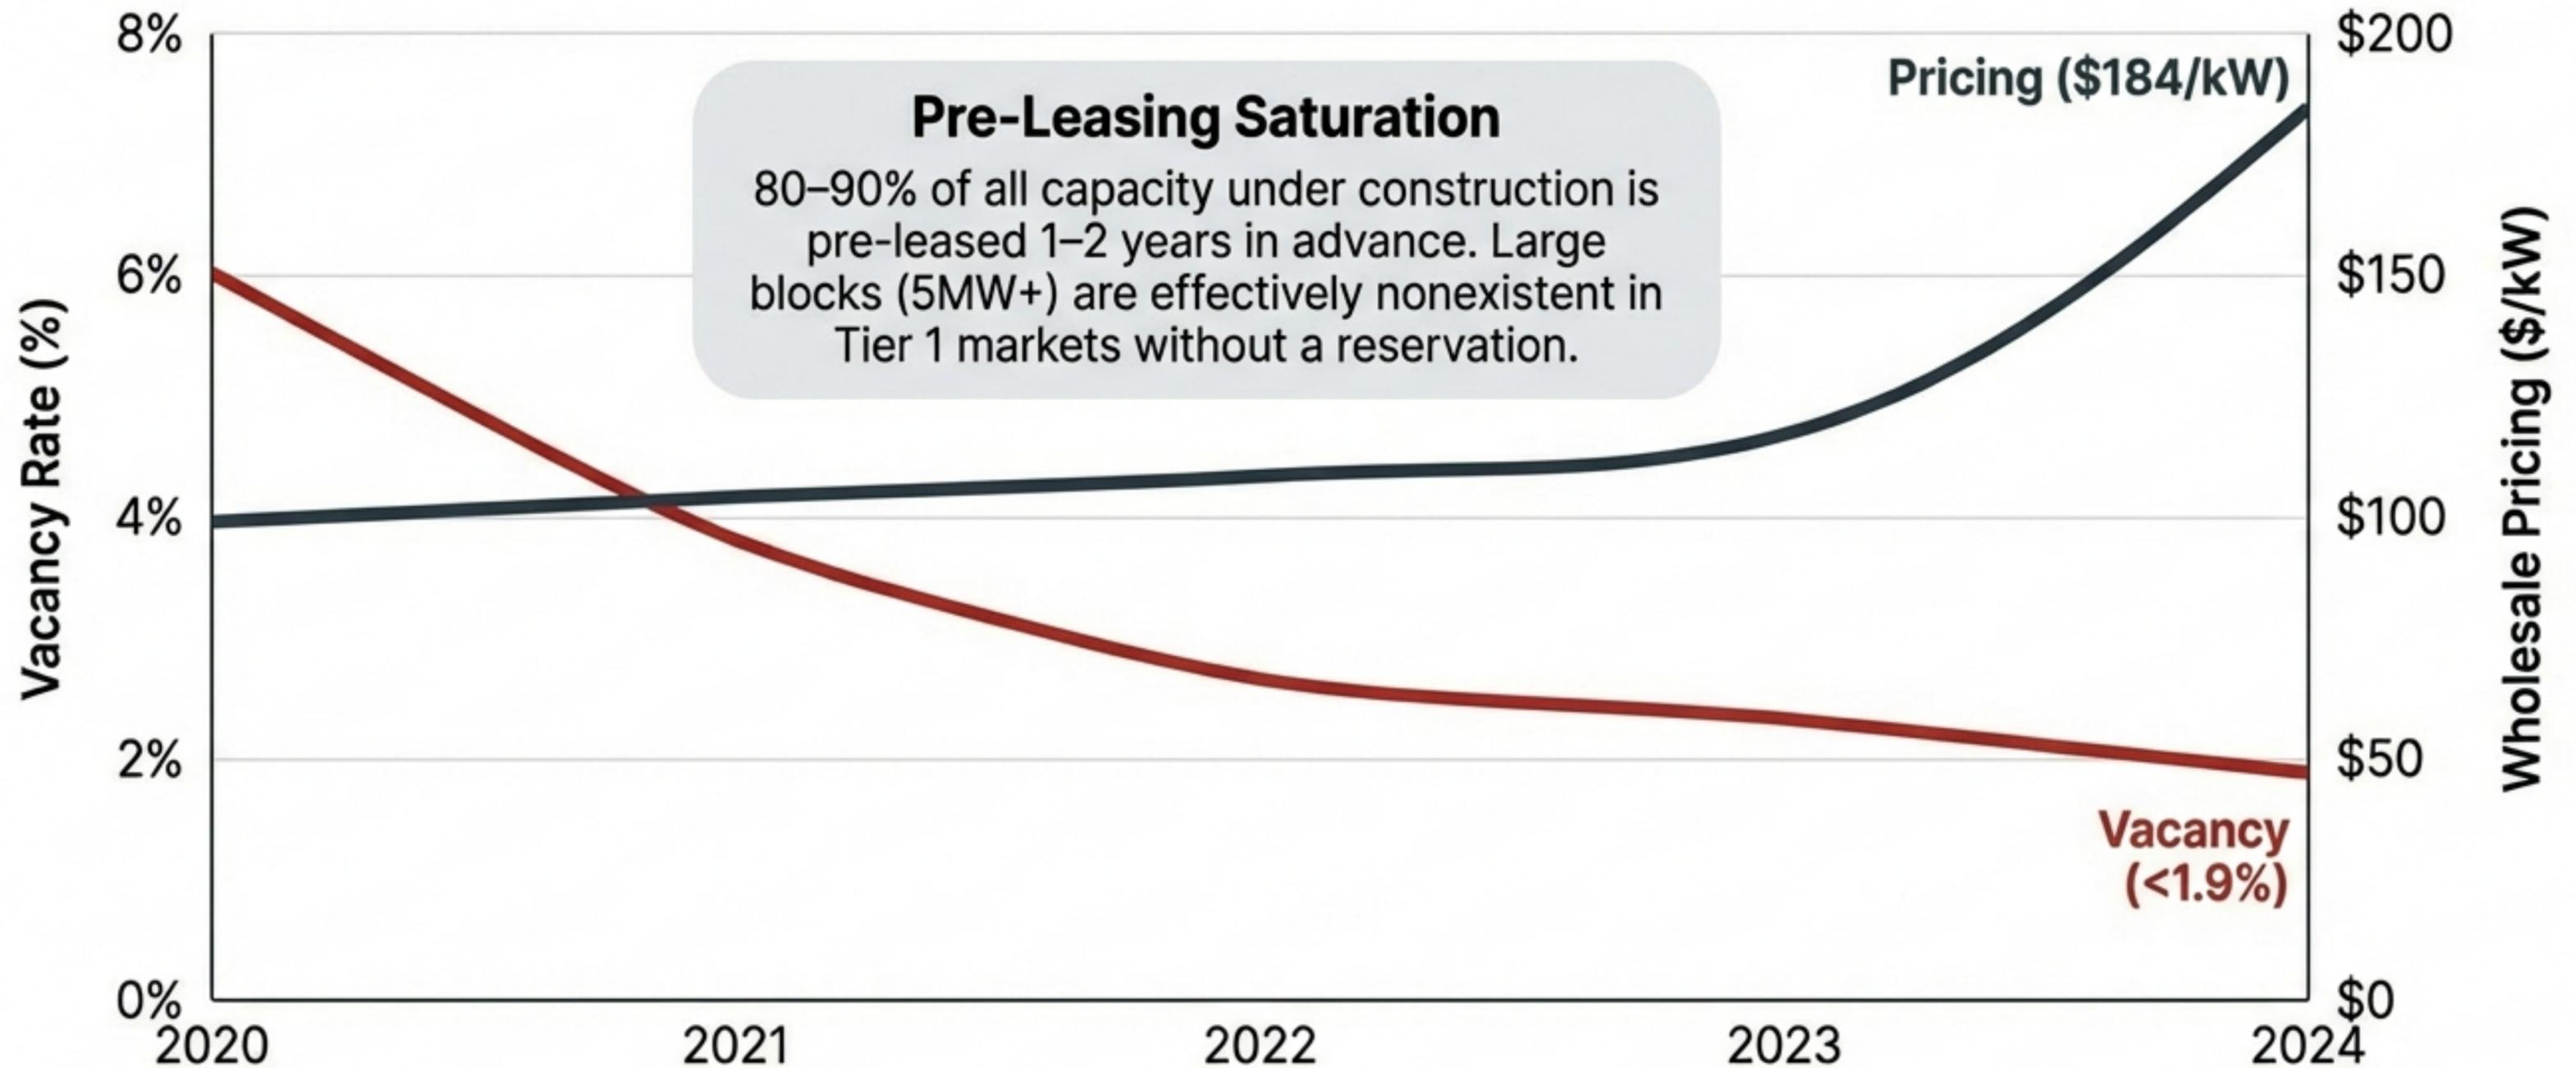

## U.S. Digital Infrastructure Capacity & Growth.

## Market Baseline (2024)

- **Valuation:** **\$70B-\$115B** (Estimated Market Value)
- **Scale:** Northern Virginia alone hosts **30 million sq. ft.** of space (Equiv. to 520 NFL fields).
- **Global Share:** North America accounts for **~50%** of worldwide capacity.

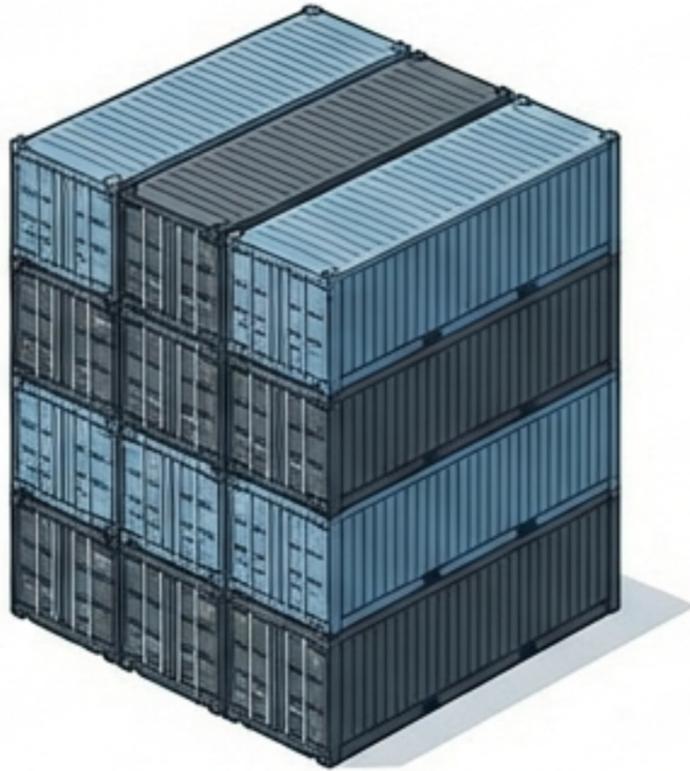

# Availability has evaporated, driving rental rates to record highs.

Hillsboro, OR saw a 46% YoY rent increase due to local supply crunch.

# The last decade was defined by Cloud Scale; the next will be defined by AI Density.

## The **Hyperscale** Era (2015–2024)

Facility physics  
are changing from  
“More Data” to  
“Hotter Data”.

- **Drivers:** Enterprise Cloud, Streaming, Mobile.
- **Net Absorption:** 330 MW (2020) → 1,800 MW (2024).
- **Metric:** Connection & Storage.

## The **AI Pivot** (2025–2030)

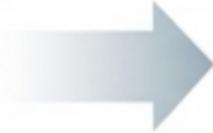

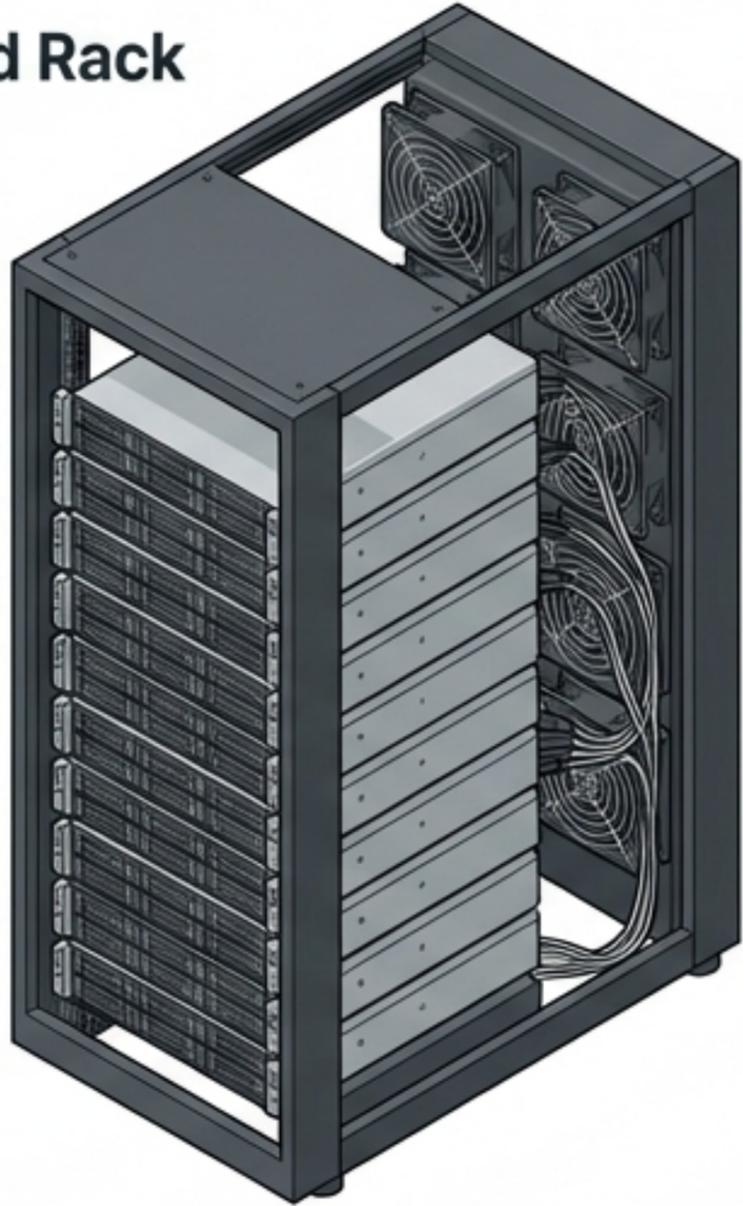

- **Drivers:** Generative AI, Large Language Models.
- **Workload Shift:** AI moves from 20% to ~50% share.
- **Metric:** Power Density & Heat.

# AI hardware is altering the fundamental physics of the facility.

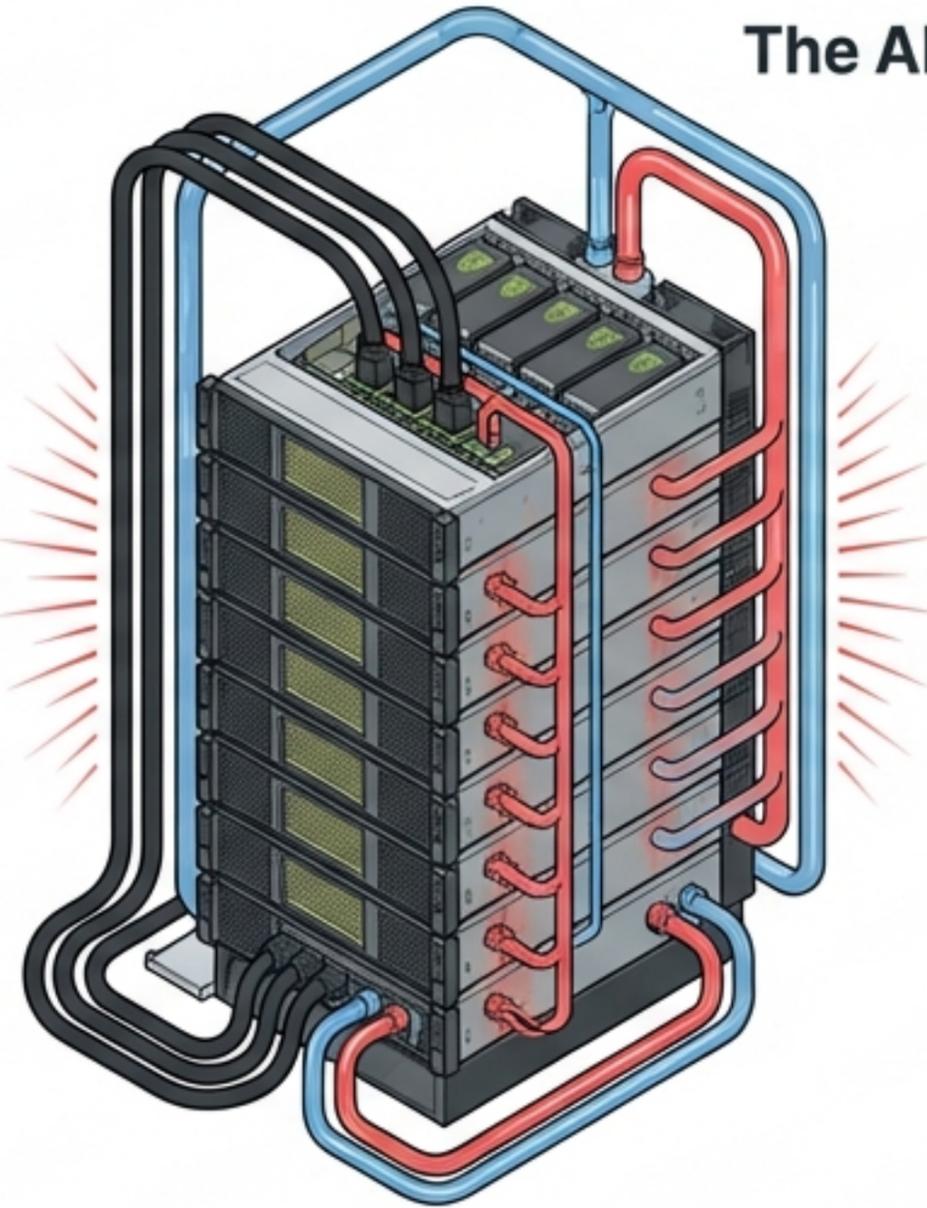

## The Standard Cloud Rack

- **Power:**  
6–12 kW
- **Cooling:**  
Air Cooled  
(CRAC/CRAH)
- **Use Case:**  
General Compute

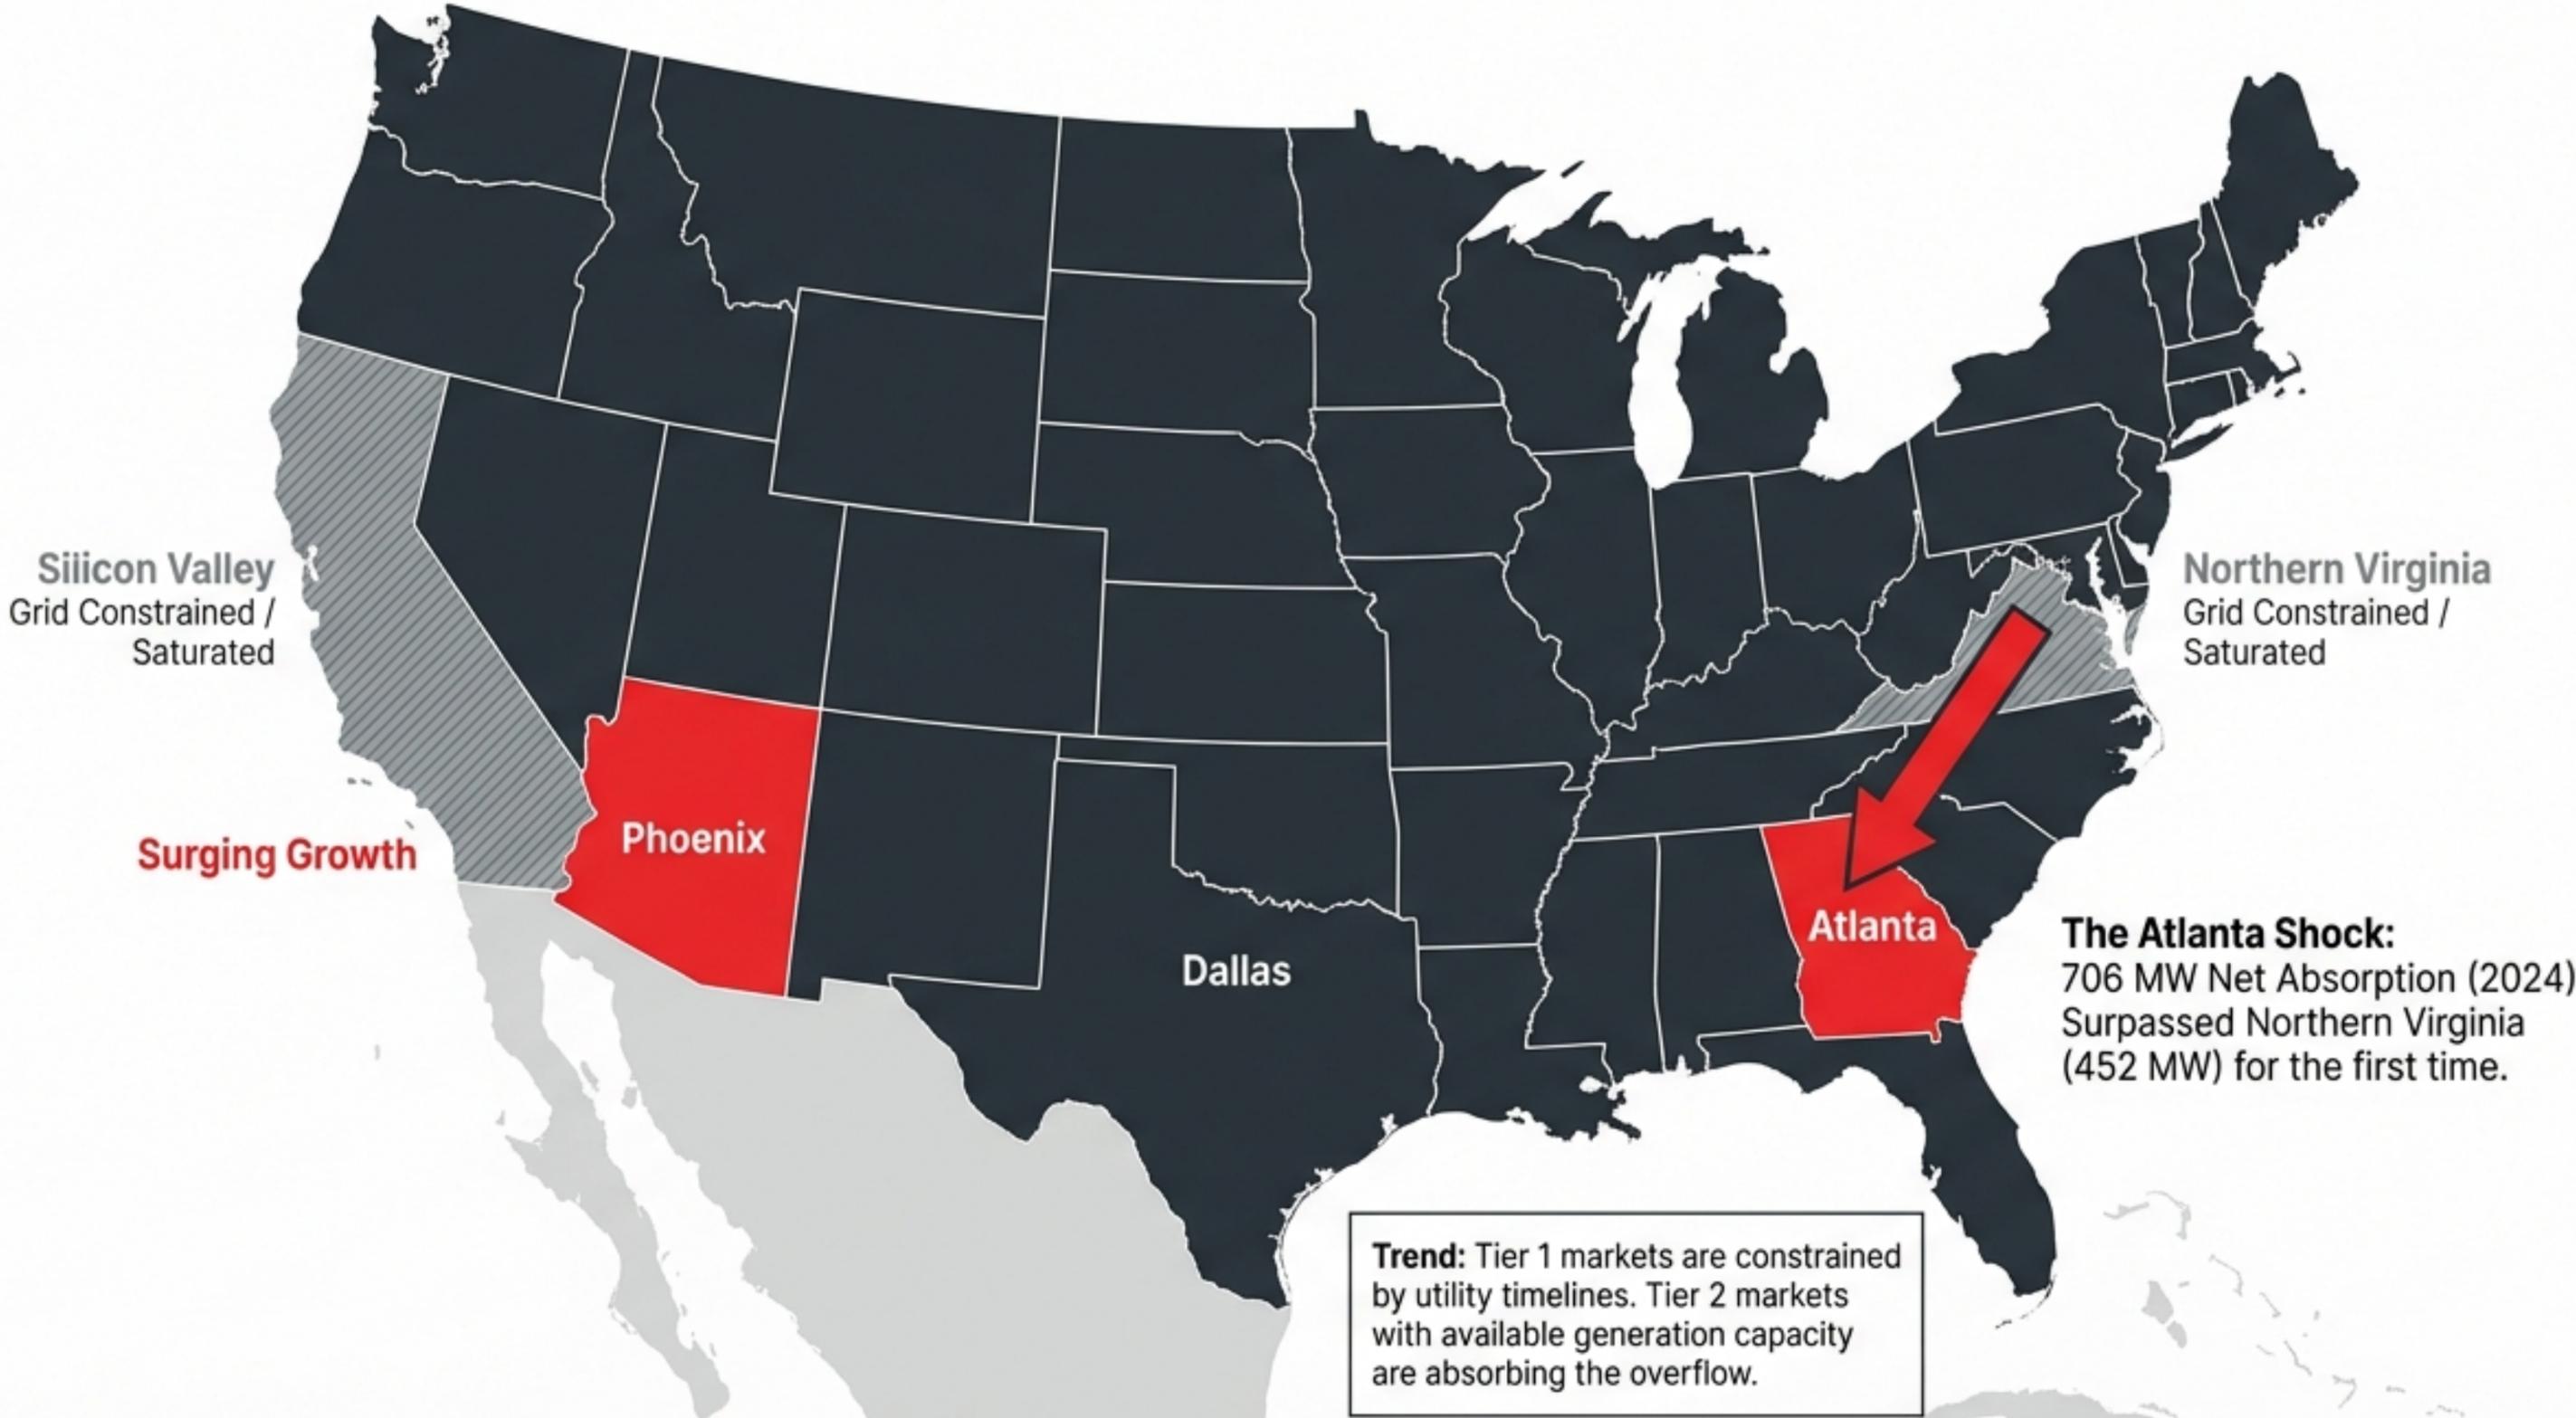

## The AI Training Cluster

- **Power:** 40–100 kW  
(NVIDIA H100s)
- **Cooling:**  
Liquid / Direct-  
to-Chip
- **Use Case:**  
Model Training

**Financial Impact:** AI-ready infrastructure costs are rising to **\$20M–\$30M per megawatt** due to electrical upgrades and cooling requirements. JLL projects 80% of new builds will require liquid cooling.

# Power availability is overthrowing the traditional hierarchy of data center hubs.

# Secondary markets are rapidly evolving into primary hyperscale targets.

Phoenix, AZ	Hillsboro, OR	Emerging Frontiers (IN & LA)
<h2 data-bbox="226 701 1002 953">+67% Inventory Growth</h2>	<h2 data-bbox="1392 701 1935 953">46% Rent Growth</h2>	<h2 data-bbox="2325 701 3092 953">Tax &amp; Power Incentives</h2>
<p data-bbox="216 1039 1012 1164"> <b>Key Driver:</b> Low Power Cost vs. California</p> <p data-bbox="216 1253 1036 1446"> <b>Constraint:</b> Water Scarcity (Driving waterless cooling)  </p>	<p data-bbox="1246 1039 2092 1215"> <b>Key Driver:</b> Connectivity Gateway to Asia </p> <p data-bbox="1246 1277 1835 1459"> <b>Status:</b> The new West Coast alternative</p>	<p data-bbox="2279 1039 3125 1178"> <b>Key Driver:</b> Speed to Power </p> <p data-bbox="2279 1240 3012 1497"> <b>Insight:</b> Indiana and N. Louisiana selected for grid capacity, not population density.</p>

**Site selection criteria** have shifted from 'Network Latency' to '**Speed to Power**'. Sites with 18–24 month utility timelines win regardless of location.

# The Grid is the Governor: A critical timeline mismatch threatens growth velocity.

## The Timeline Gap

- Data centers projected to consume 6–12% of total U.S. electricity by 2028.
- **NERC Warning:** Rapid load growth threatens grid reliability.
- **Reality:** Record capacity is under construction, but significant portions sit idle waiting for “will serve” dates.

# Supply chain friction is elongating project schedules by nearly 50%

## Lead Time Comparison

■ Pre-2020 ■ Current

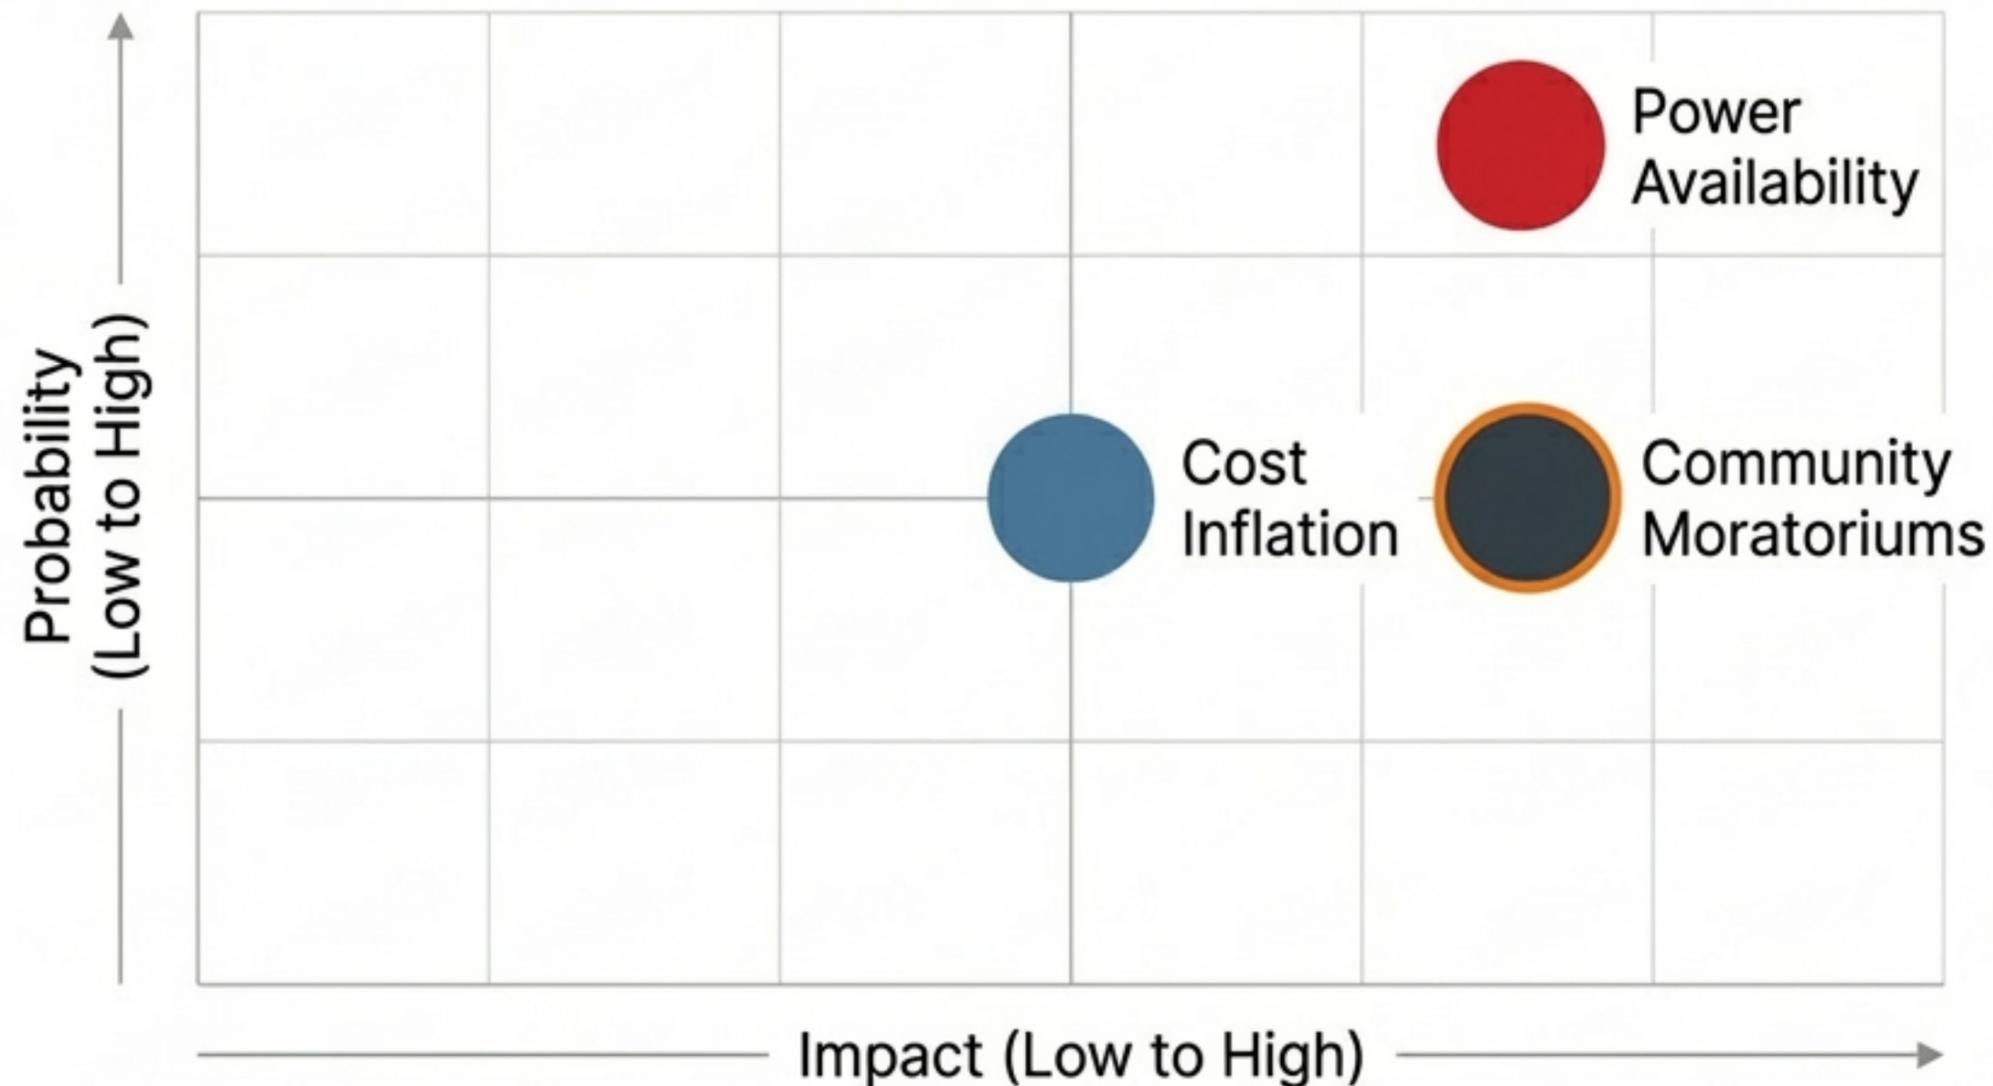

Operators are adapting by **stockpiling** equipment (6–12 months inventory) and entering “**shared risk**” co-investment deals with manufacturers.

The industry is effectively Time-to-Power constrained, not capital constrained.

# Regulatory friction and community pushback pose rising threats to development.

## Risk Matrix

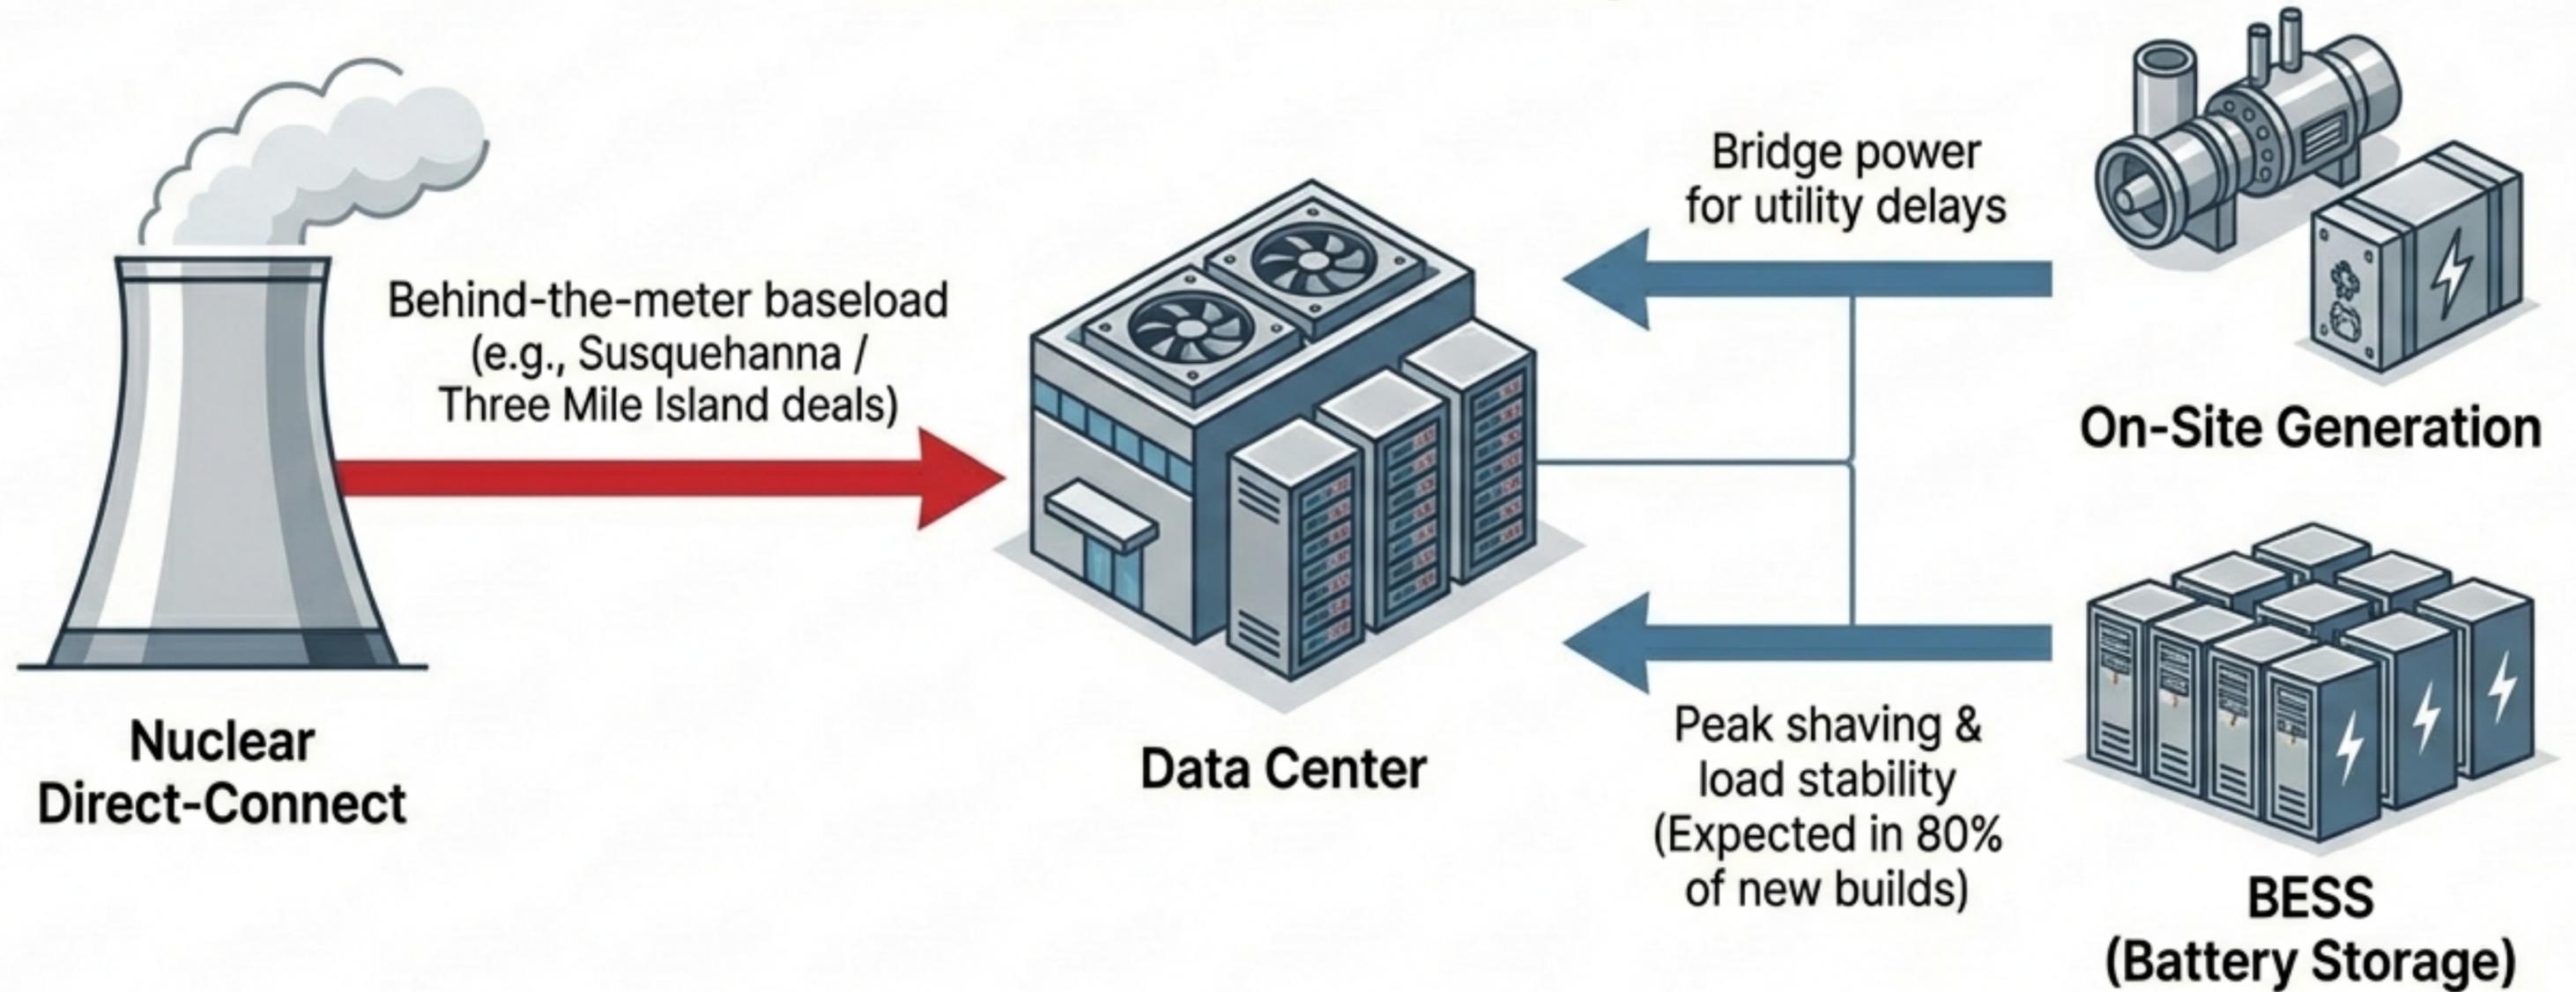

### The “Good Neighbor” Problem:

16+ projects worth \$64B have been delayed by local opposition.

**Issues:** Noise ordinances (NoVa), Water usage (West), and “Energy Hog” perceptions increasing utility bills for residents.

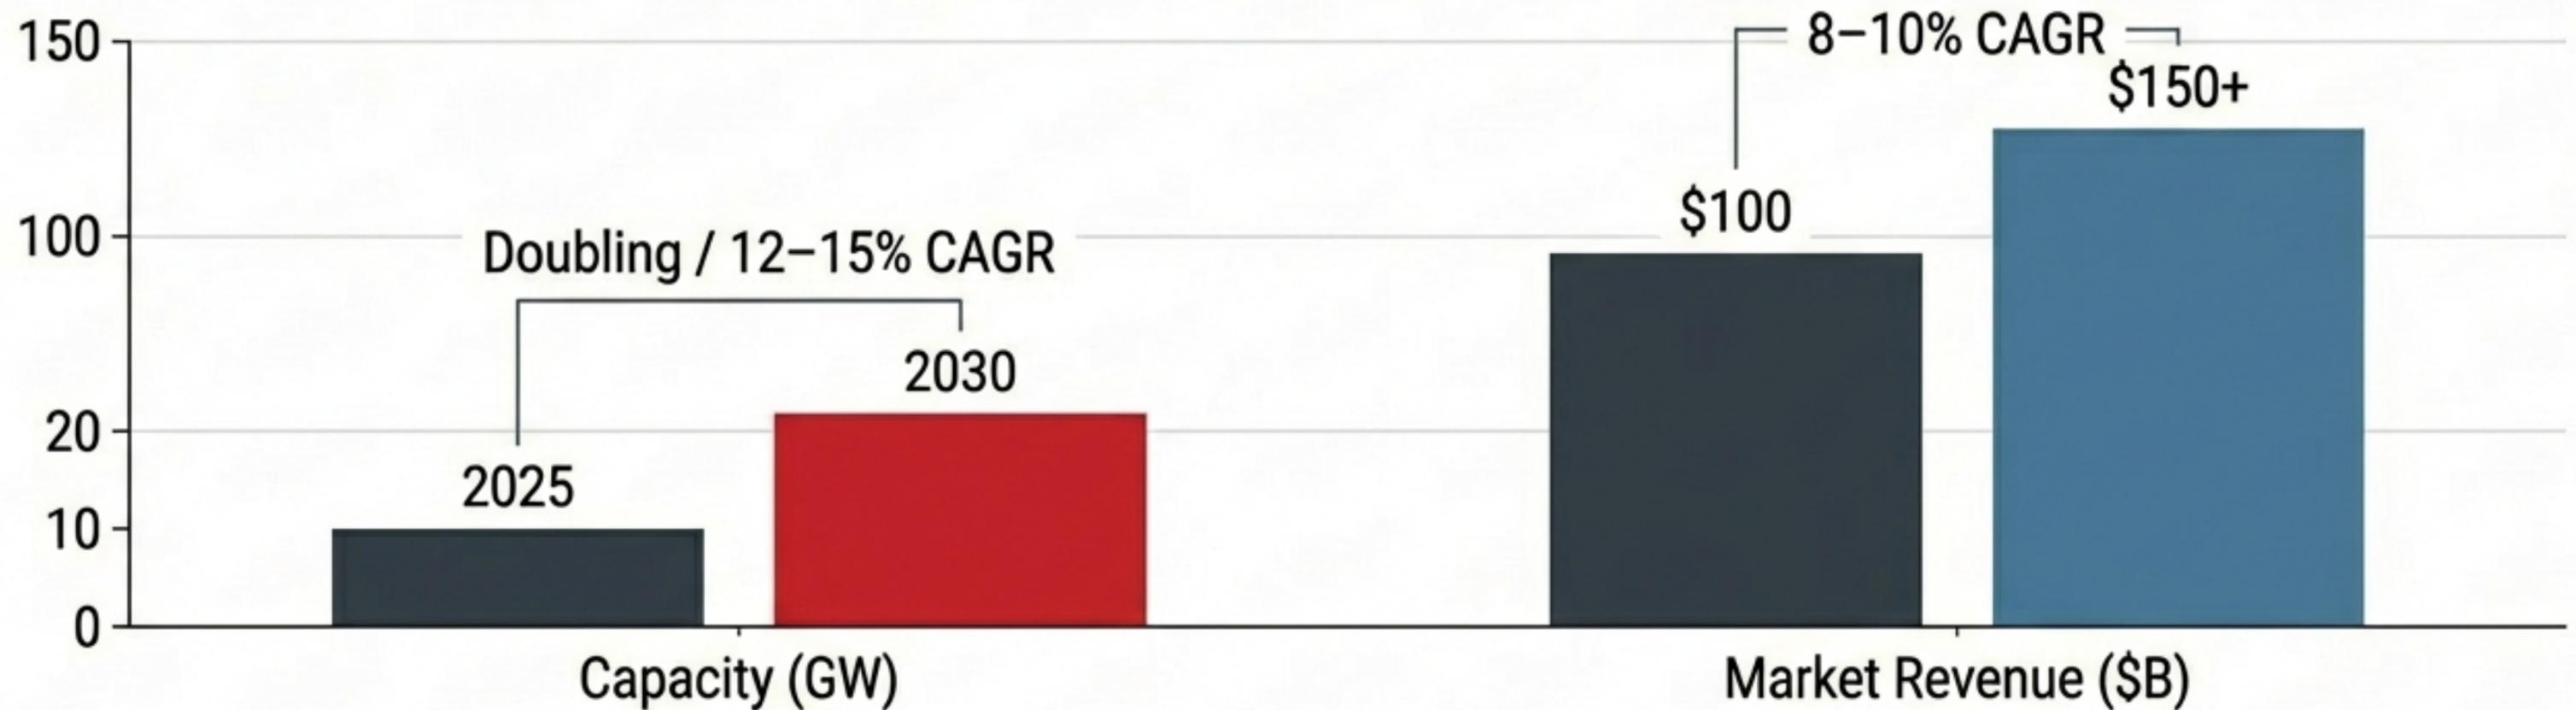

# Operators are bypassing the grid with on-site generation and nuclear partnerships.

## Next-Gen Resilient Campus

# The Base Case: Capacity doubles by 2030, driven by the AI integration.

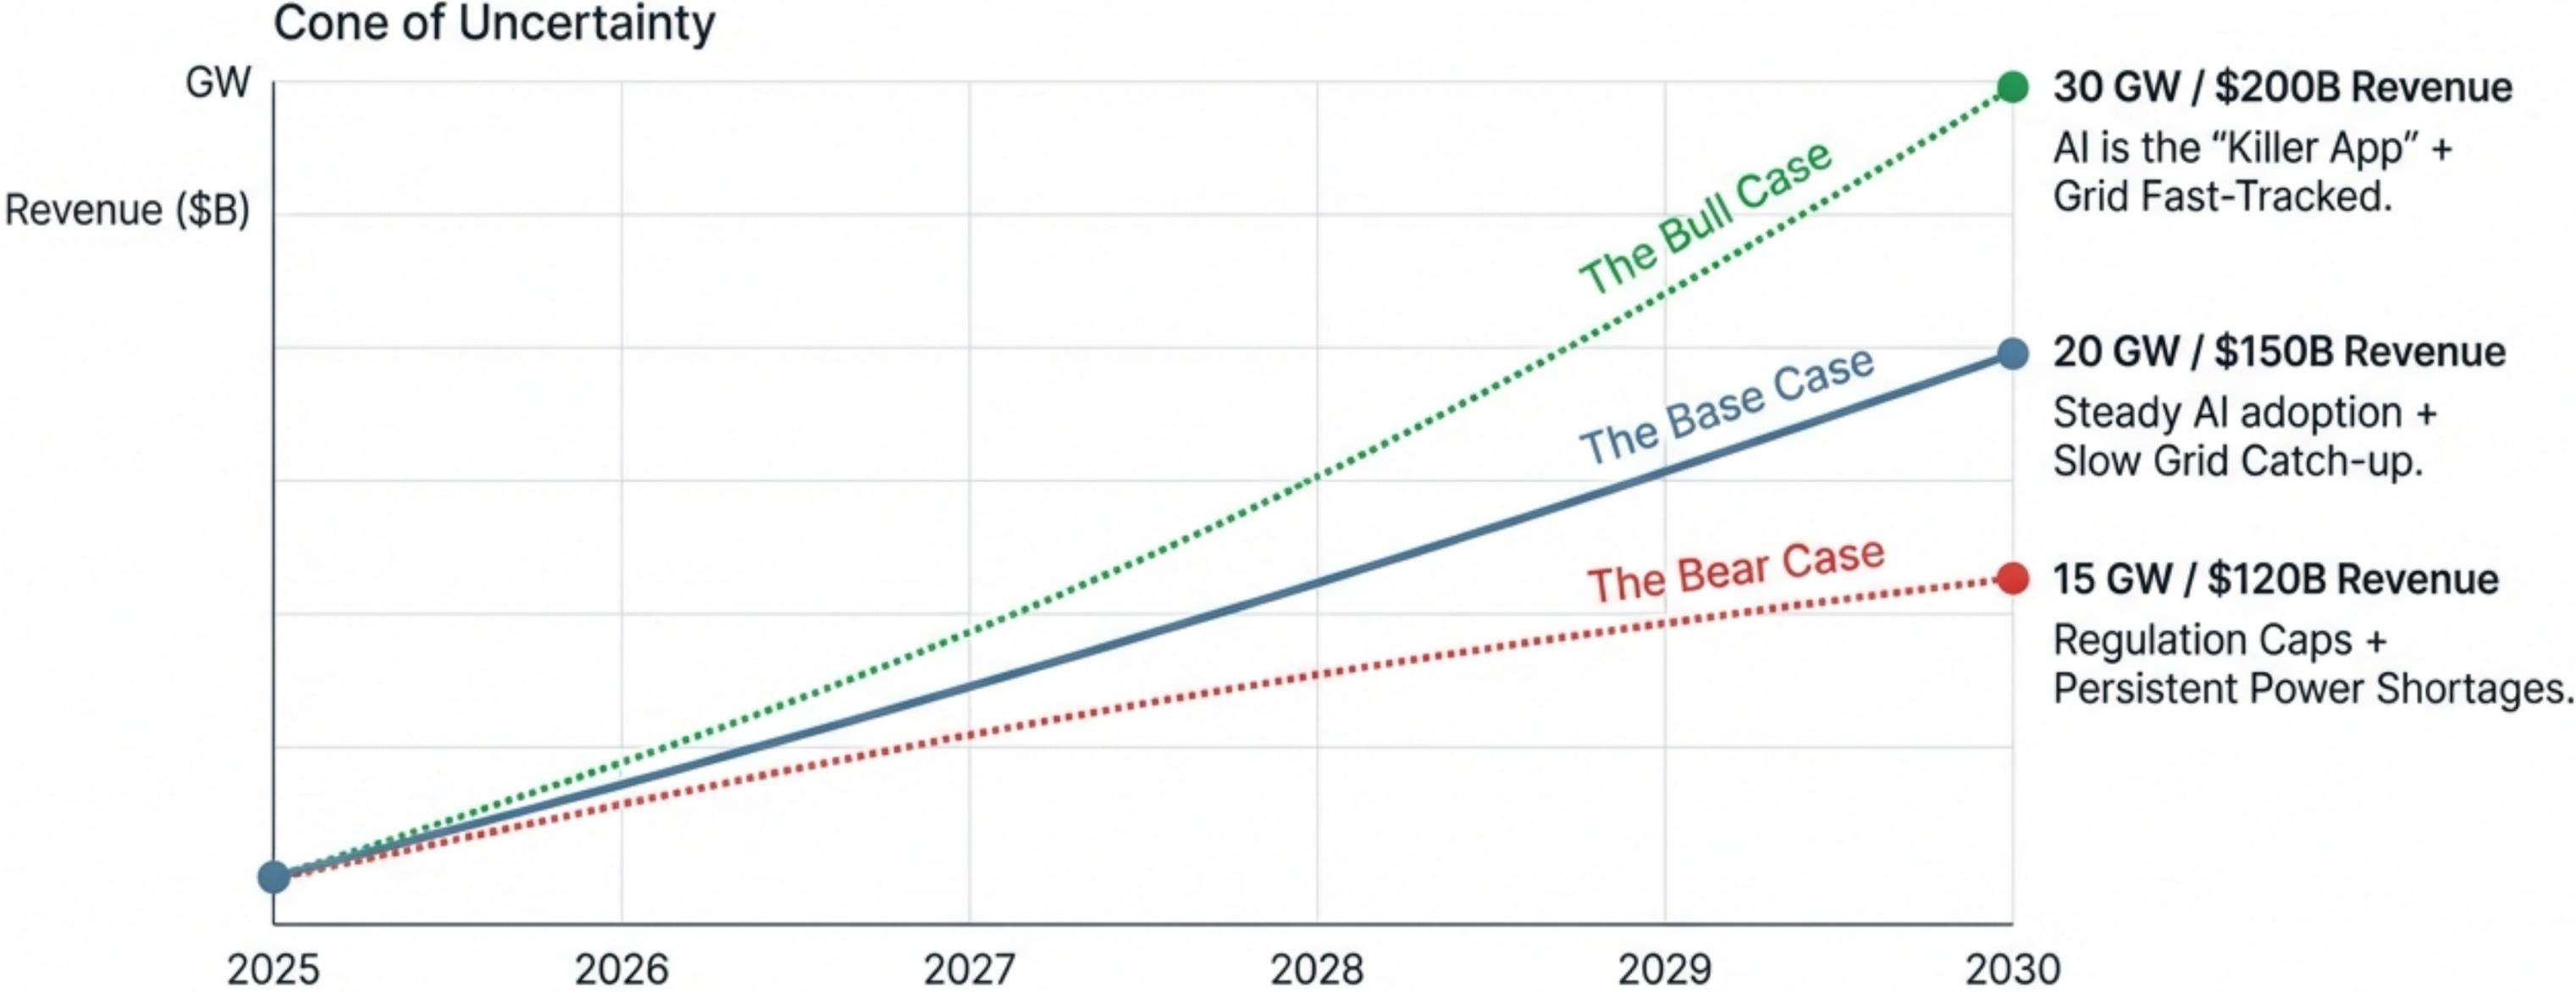

## Projections: 2025 vs. 2030

### Key Assumptions:

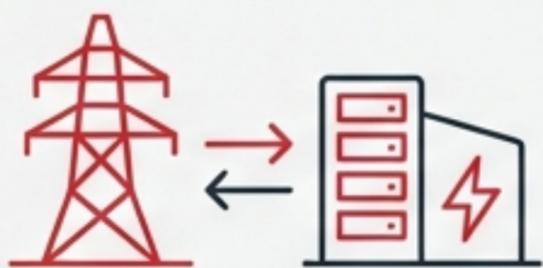

1. AI workloads reach 50% of total demand.
2. Grid upgrades catch up slowly (NoVa relief by 2026/27).
3. Utilization remains high; vacancy stays low single-digits.

# Market trajectory hinges on two variables: AI adoption speed and Grid flexibility.

Even the downside scenario represents growth; the digital trend is secular, but the slope is determined by infrastructure policy.

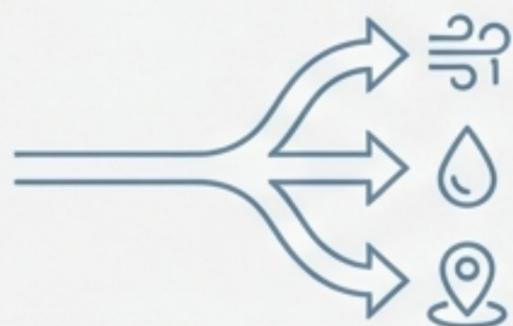

# Navigating the Power Pivot: Strategic Imperatives for 2030

## 1

### **Power Dictates Strategy**

Sourcing gigawatts is now more complex than sourcing silicon. Site selection is an energy problem, not a real estate problem.

## 2

### **Flexibility is Survival**

Success requires technical flexibility (liquid cooling readiness) and geographic flexibility (willingness to leave Tier 1 hubs for Tier 2 power availability).

## 3

### **Efficiency as a License to Operate**

Sustainability is no longer PR; it is a regulatory requirement to avoid moratoriums and community rejection.

**The U.S. data center sector is the backbone of the 21st-century economy, but the easy growth is over. The next phase requires engineering resilience.**
